

The goal of this is to see how best readable can you write.
Breaking the problem into sub-problems and writing sub-functions
and comments will make it readable code.

```
// Convet given large binary number into hexadecimal number.
```

```
// e.g:
```

```
// Input: "01010101010", Output: "0x2AA"
```

```
char *convertToHex(char *binary_number);
```

```
// Find second maximum digit in the given hexadecimal number.
```

```
// e.g:
```

```
// Input: "0xABC3249", Output: 'B'
```

```
char second_max_digit(char *hex_number);
```

```
// Delete all the second maximum digit in the given hexadecimal number.
```

```
// update the given hex_number array.
```

```
// e.g:
```

```
// Input: "0xAABBCC99", Updated: "0xAACC99"
```

```
// Note: Use the above function second_max_digit, to solve this.
```

```
void delete_second_max_digits(char *hex_number);
```

```
// Note: You need to write two solutions for this problem
```

```
// Note: your code must work when a large file contains everything in a single  
line.
```

```
// Given a file as input, generate an output file.
```

```
// Replace each space with line number in which it exists.
```

```
// e.g:
```

```
// sample input file containing these two lines.
```

```
// we have become comfortable at coding
```

```
// need to write code daily
```

```
//
```

```
// output file must contain these two lines.
```

```
// we1have1become1comfortable1at1coding
```

```
// need2to2write2code2daily
```

```
//
```

```
// Return
```

```
// 1 - On Success
```

```
// 0 - On Failure
```

```
int replace_space_with_line_number(char *input_file_name, char  
*output_file_name);
```
